Linking Databases to Maps

Thematic Maps and Map Layers

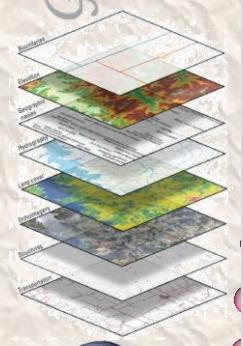

Map Scale and Resolution

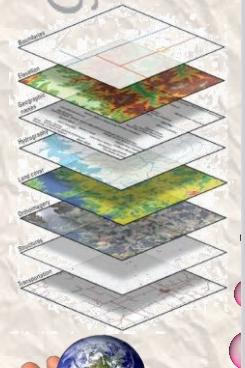

Vector vs. Raster Resolution

Scale vs. Resolution

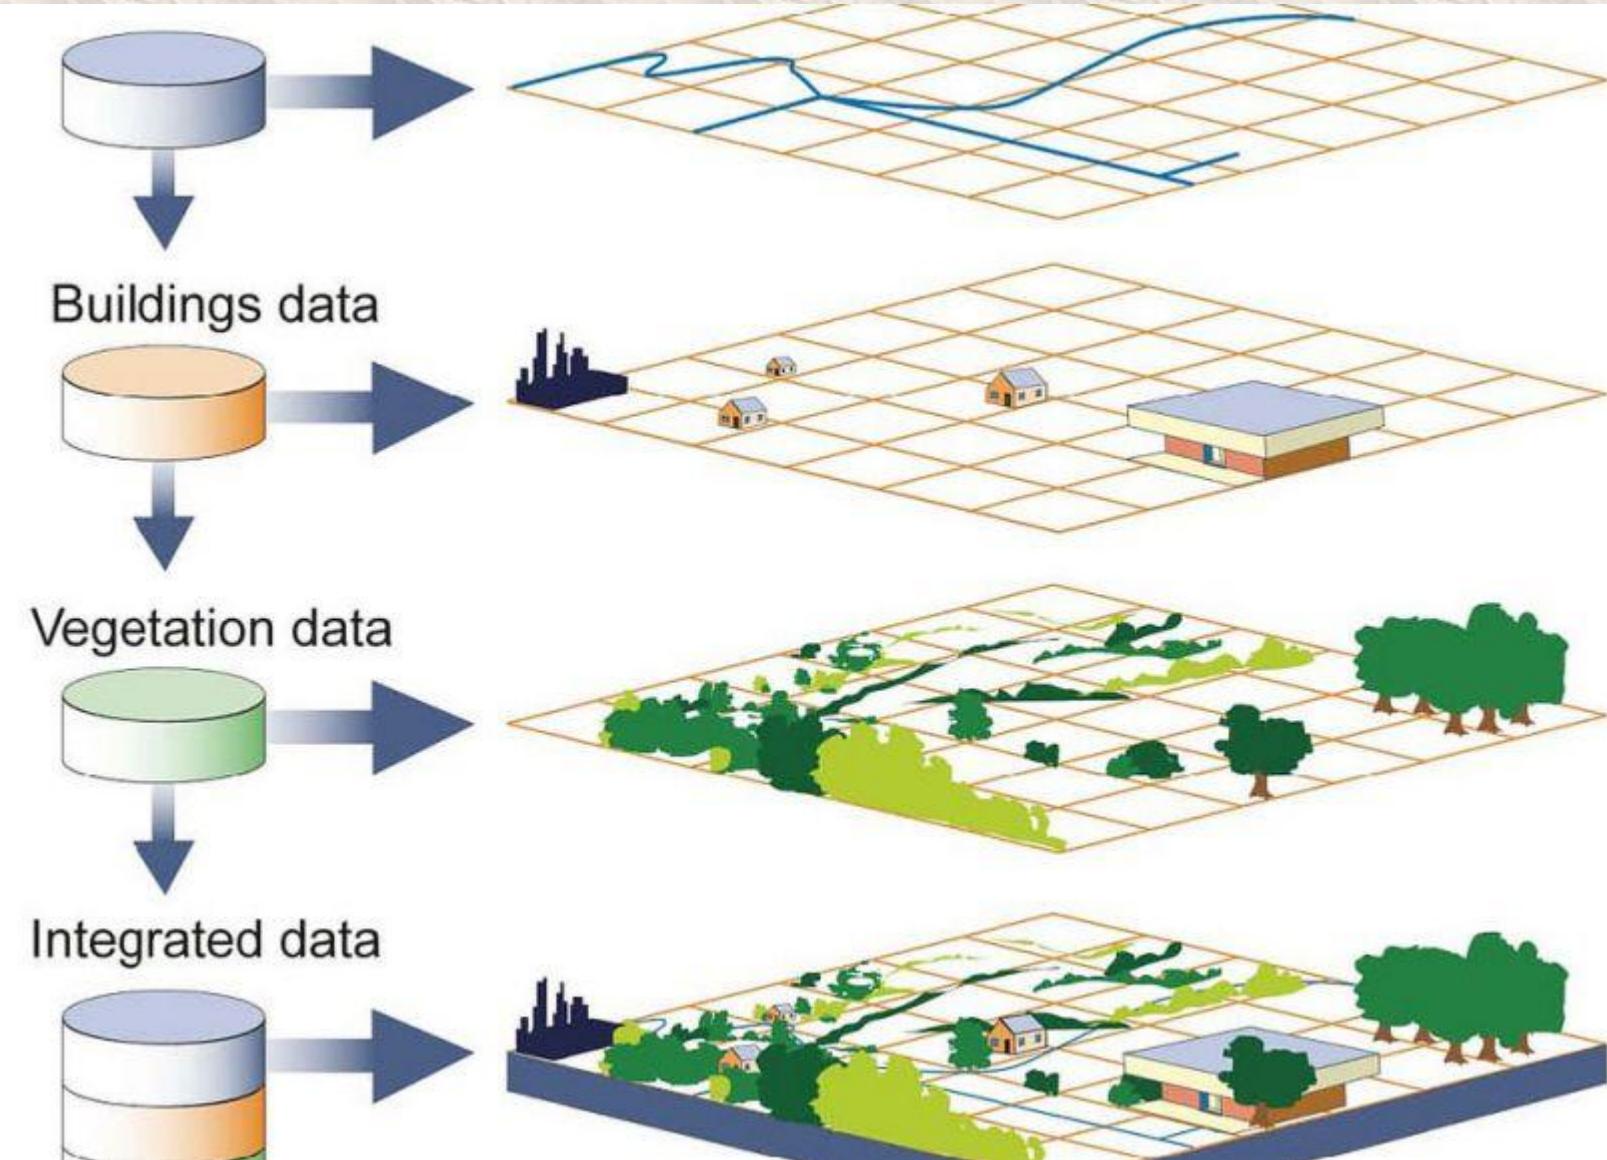

Representing Geographic Phenomena

Key Takeaways

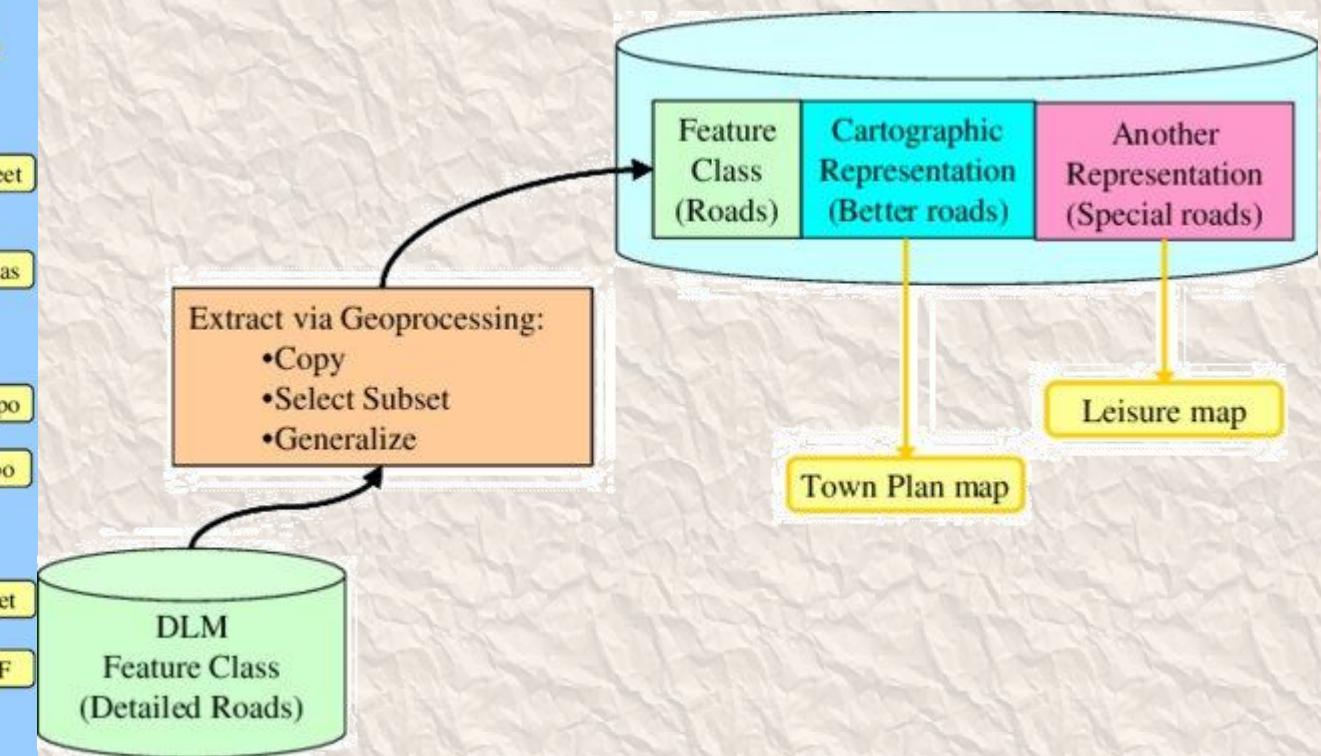

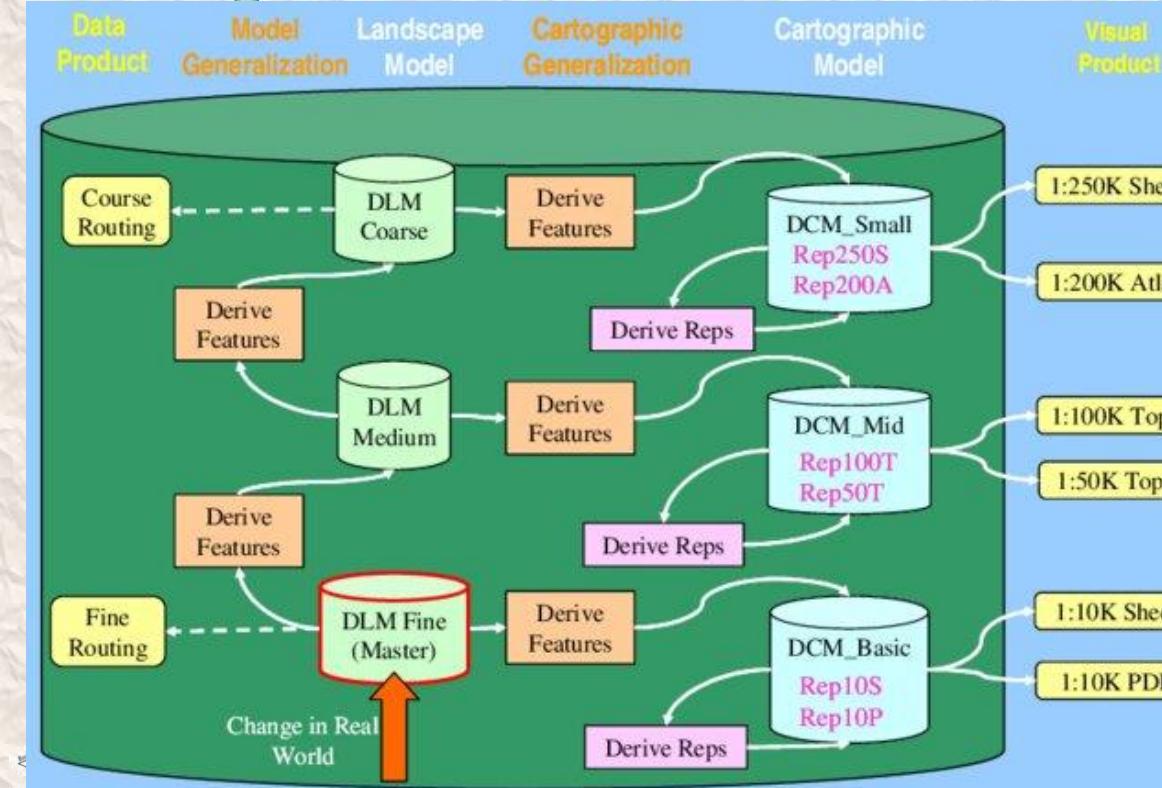

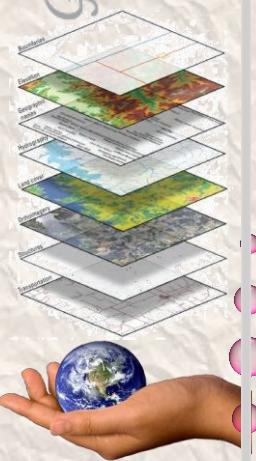

Database and Mapping Concepts

Database and Mapping Concepts

Linking Databases to Maps

- GIS integrates geographic features (points, lines, polygons) with attribute data (e.g., name, category).
- Enables maps to show not just where things are, but what they are.
- Uses unique identifiers (IDs) to connect spatial features to database entries.
- Two primary data models:
 - Vector: Discrete features with geometry (points, lines, polygons).
 - Raster: Grid cells representing continuous phenomena (e.g., elevation, land cover).

- # Thematic Maps and Map Layers
- Reference maps: Show general features (e.g., topographic maps).
 - Thematic maps: Focus on one topic (e.g., population density, rainfall).
 - Thematic mapping uses visual variables (color, pattern, size).
 - Common types: choropleth, dot density, proportional symbols, flow maps.
 - GIS layers:
 - Each represents a single data theme (e.g., roads, rivers, land use).
 - Can be stacked, symbolized, and analyzed together.
 - Example: Narayangadh City mapping with multiple layers (built-up, roads, land use)

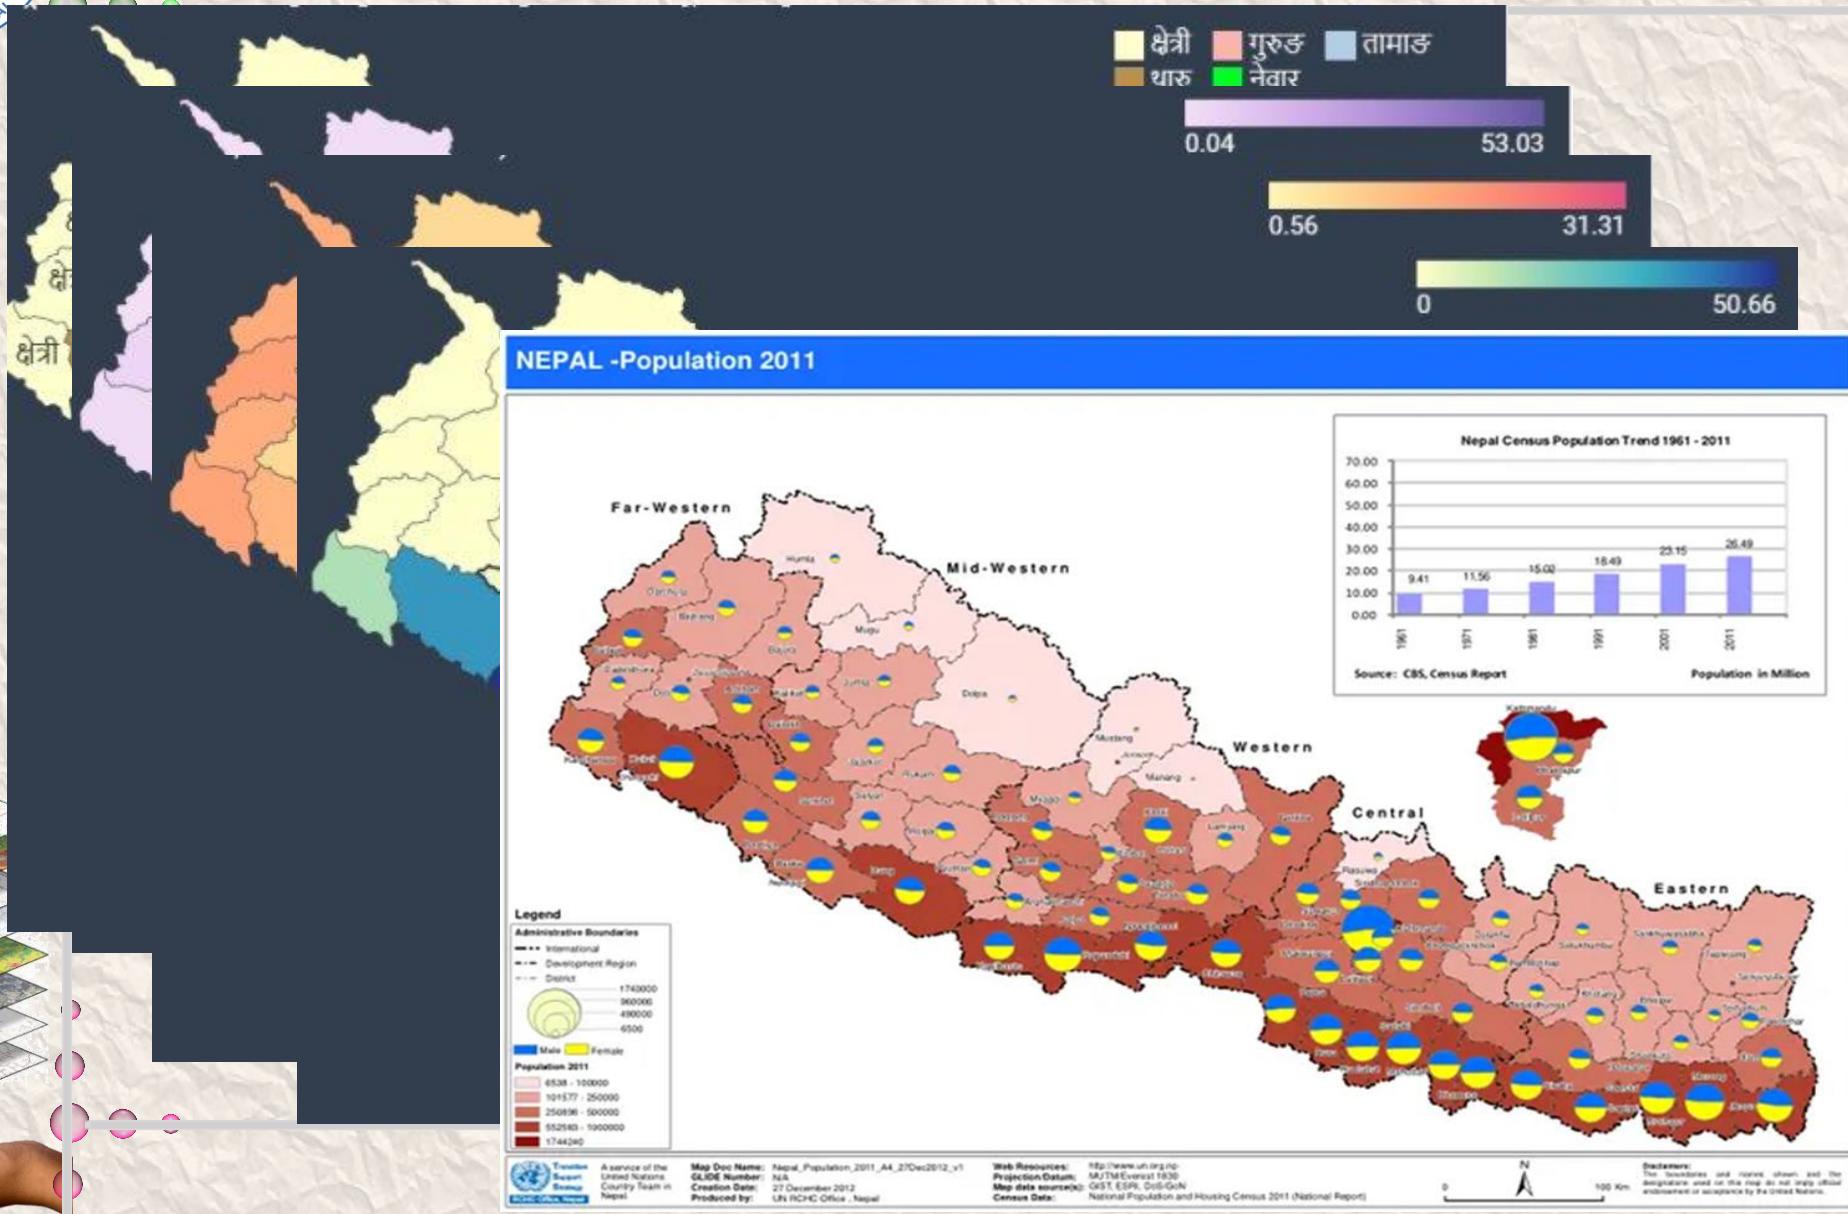

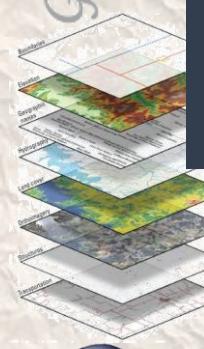

Reference maps

A screenshot of a Microsoft Word ribbon toolbar. The toolbar includes icons for drawing tools like text boxes, shapes, and arrows, as well as font and size dropdowns set to "Arial" and "10". There are also buttons for bold, italic, underline, and strikethrough, along with a font style dropdown showing "A" and "B".

Map Scale and Resolution

- Scale = Map distance vs. ground distance (e.g., 1:50,000).
 - Large scale: Zoomed in, high detail (e.g., 1:10,000).
 - Small scale: Zoomed out, low detail (e.g., 1:5,000,000).
- GIS maps are scalable, but each view has a display scale.
- Symbol sizes and detail must match the intended display scale.
- Resolution = Smallest unit represented (esp. in raster data).
 - High resolution = finer detail (e.g., 10×10 m pixels).
 - Low resolution = generalized view (e.g., 1 km pixels)

Three ways of expressing

Three Types of Scale

There are three different ways to write scale.

Word Scale

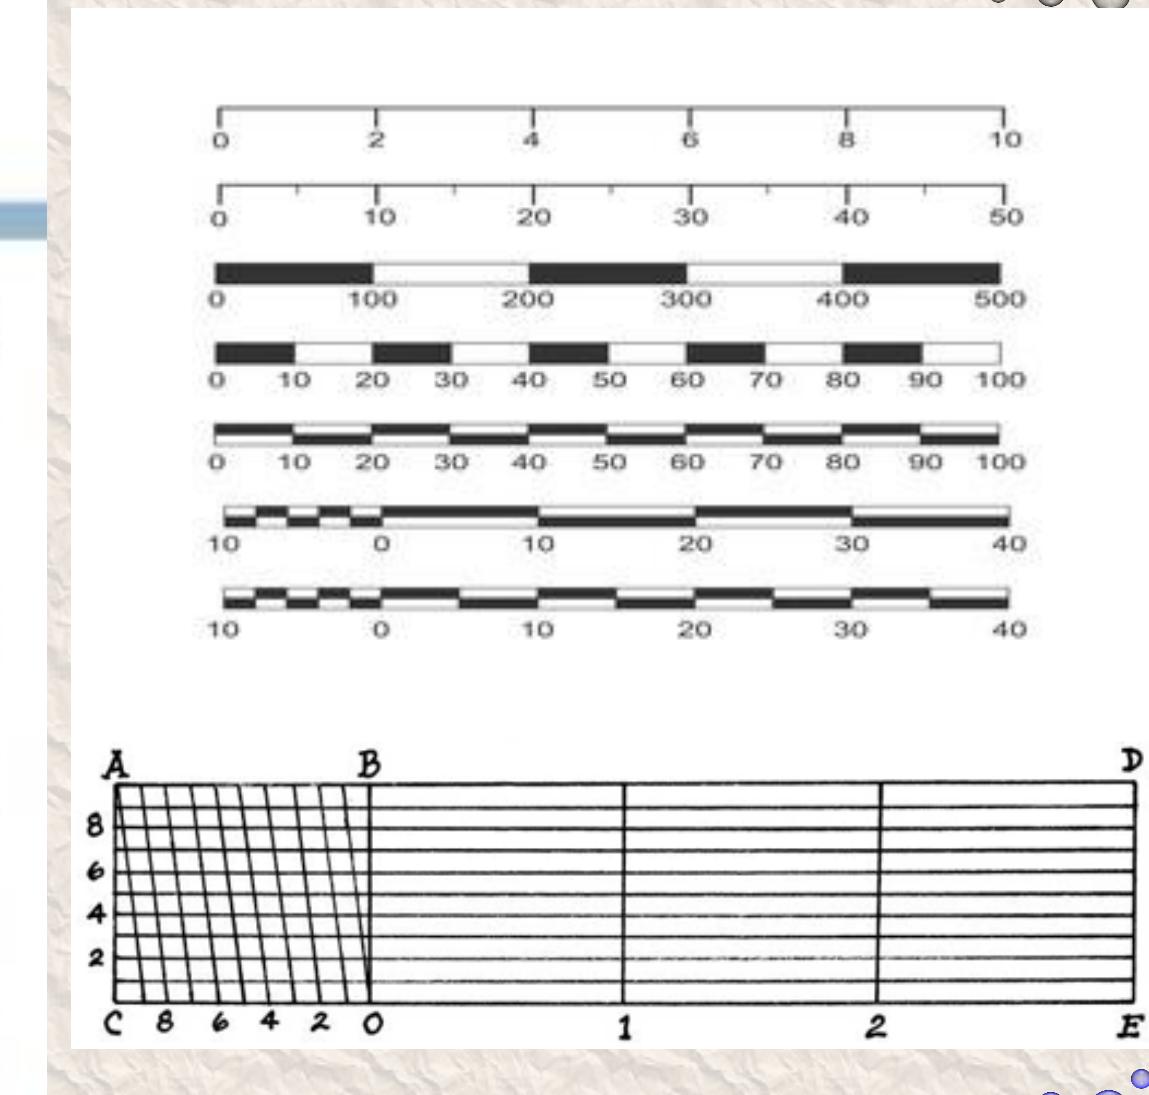

• 1 cm = 250 km

Linear Scale or Bar Scale

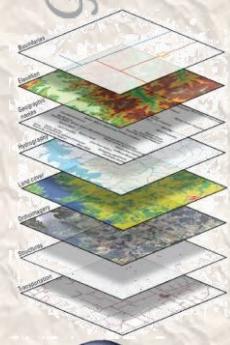

Ratio Scale or Representative Fraction Scale

• 1:25 000 000

Symbol sizes and detail must match the intended display scale

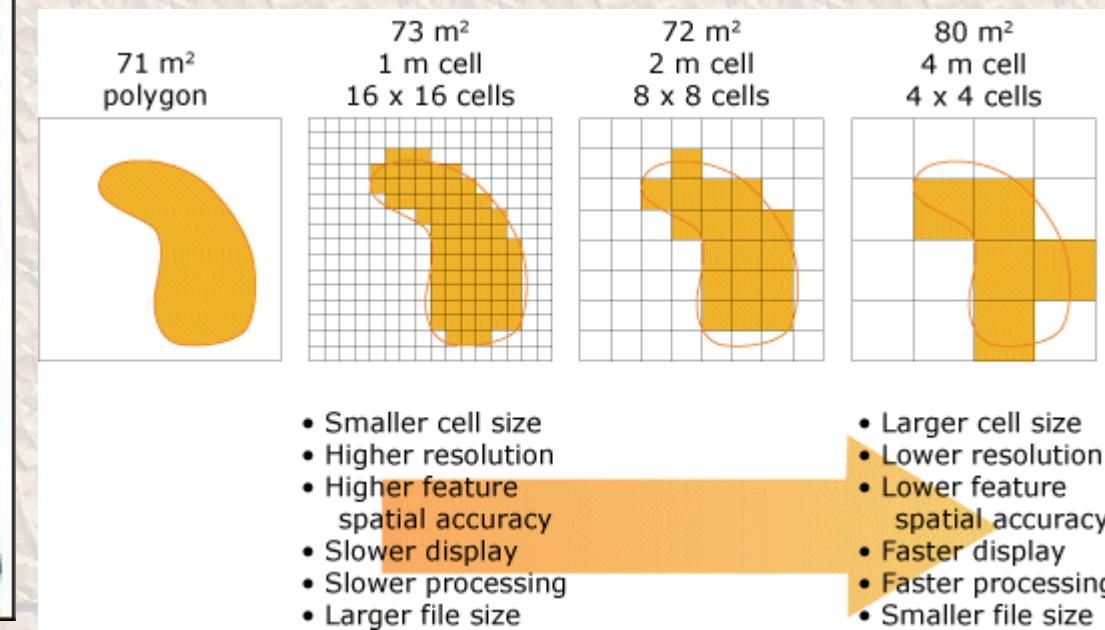

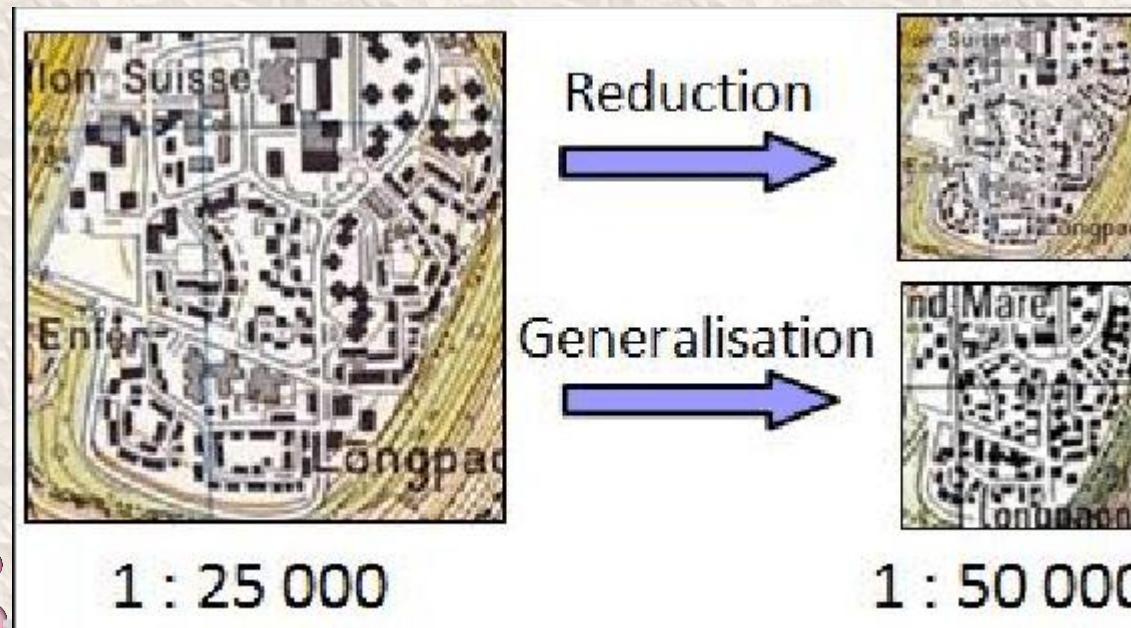

Vector vs. Raster Resolution

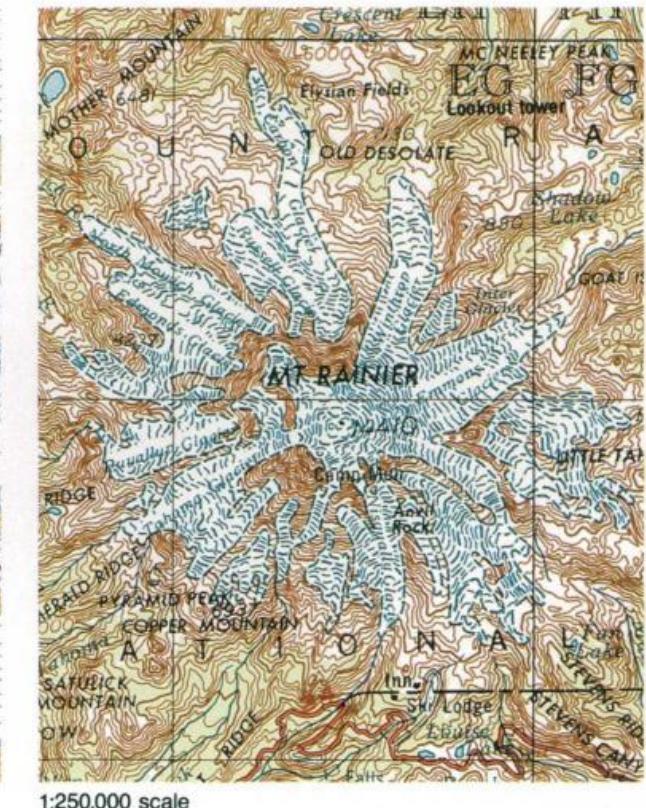

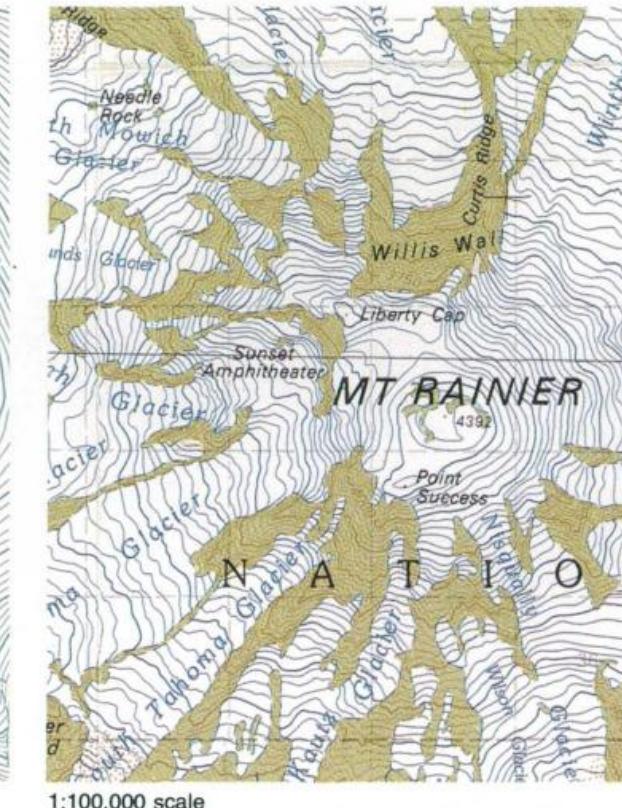

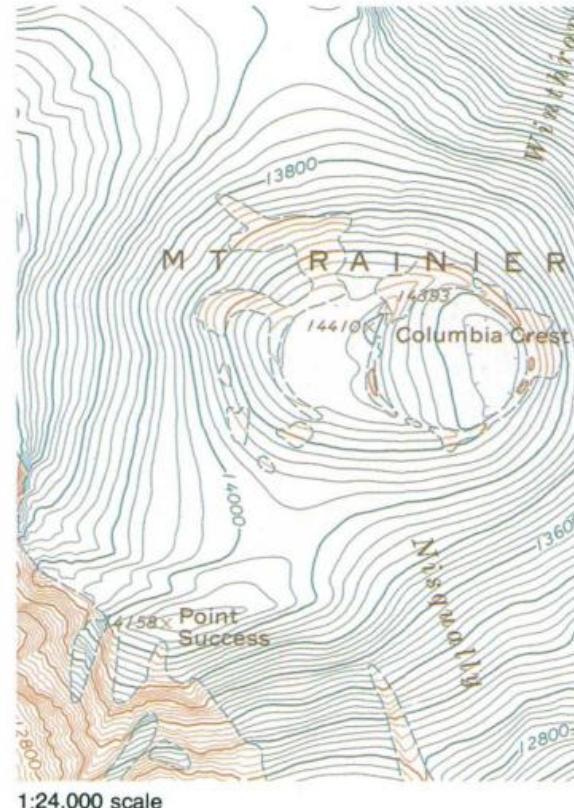

- Vector data has no fixed resolution but varies in detail/precision.
 - Curves and edges are simplified or generalized based on capture scale.
 - Example: A river digitized from a 1:50,000 map is more detailed than from 1:1,000,000.
 - Generalization is key when moving to smaller scales.

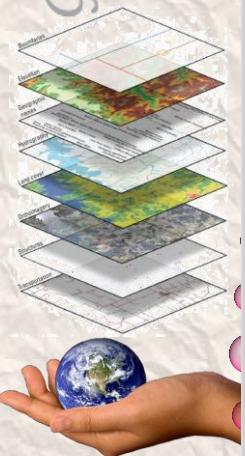

Scale vs. Resolution

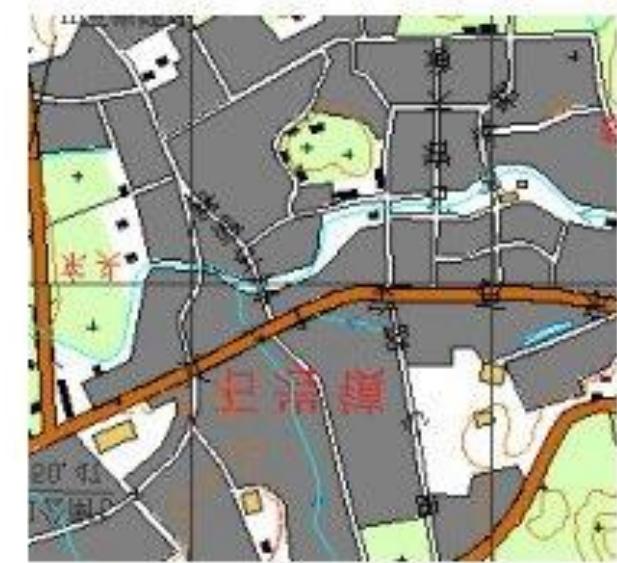

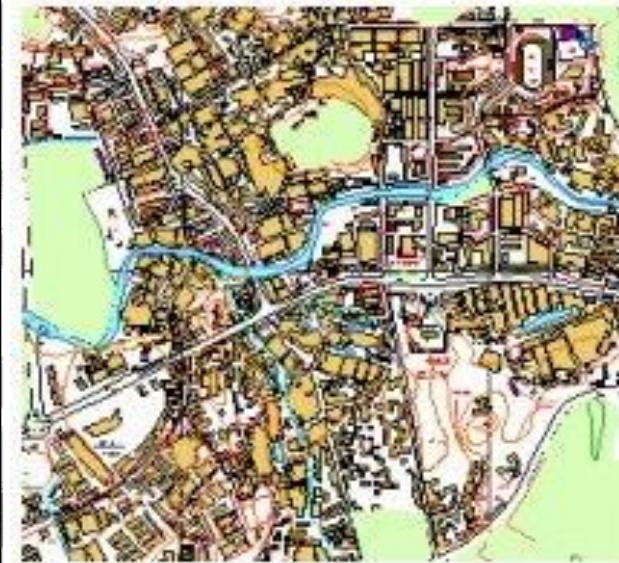

- Scale and resolution are interlinked.
 - Small-scale maps can't show high-resolution features without clutter or false precision.
- Good practice: Match data resolution with map scale to ensure clarity and accuracy.

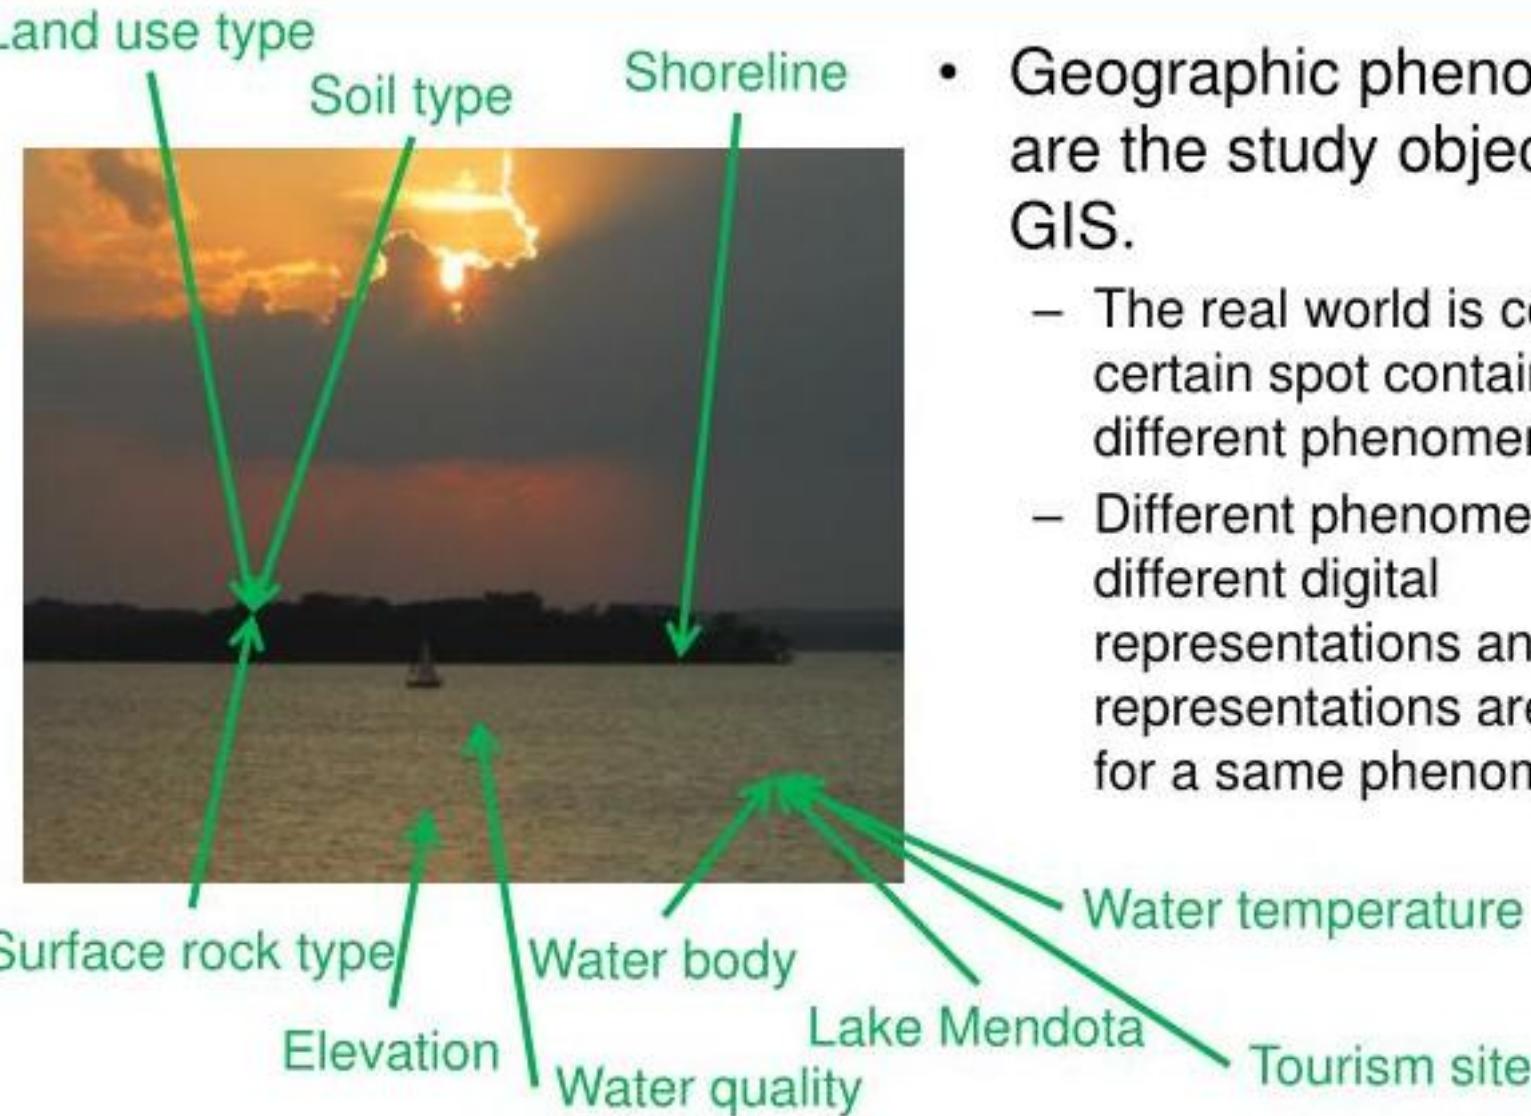

Spatial and Attribute Transformations (Generalization Operators)	Representation in the Original Map		Representation in the Generalized Map
	At Scale of the Original Map	At 50% Scale	
Simplification

Displacement			
Classification	1,2,3,4,5,6,7,8,9,10,11,12, 13,14,15,16,17,18,19,20	1-5, 6-10, 11-15, 16-20	Not Applicable

Scale vs. Resolution

Representing Geographic Phenomena

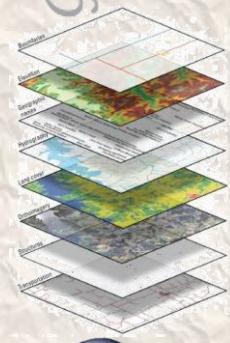

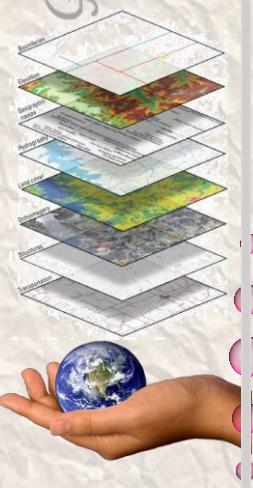

- Geographic phenomena are the study objects of a GIS.
 - The real world is complex. A certain spot contains many different phenomena.
 - Different phenomena require different digital representations and multiple representations are possible for a same phenomenon.

Representing Geographic Phenomena

- Discrete features → often represented with vector (e.g., buildings, roads).
- Continuous surfaces → typically raster (e.g., elevation, temperature).
- Choice depends on:
 - Nature of data (continuous vs. discrete).
 - Scale and purpose of the map.
- Example: Elevation of the Himalayas
 - at national scale = raster DEM;
 - at district scale = contour lines.

Key Takeaways

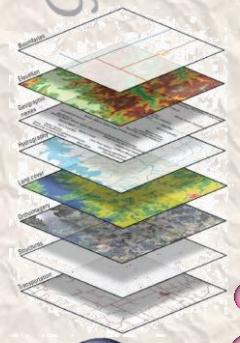

- **Features & Attributes:** Core of GIS — location + descriptive data.
- **Thematic Mapping:** Visualizes a specific attribute using map symbology.
- **Layered Structure:** Enables overlay, spatial queries, and composite mapping.
- **Scale Awareness:** Align data detail with map's visual purpose.
- **Resolution Matters:** Use suitable resolution — not too coarse or overly detailed.
- **Representation Choices:** Match data type (vector/raster) to phenomenon and analysis goal.
